ABSTRACT
Natural product compounds obtained from medicinal plants have been great contributions in the discovery of numerous clinically useful drugs. Markhamia species have been reportedly used by many cultures in human and veterinary traditional medicines. The five identified species of Markhamia, that is, Markhamia lutea, Markhamia obtusifolia, Markhamia stipulata, Markhamia tomentosa, and Markhamia zanzibarica have been the subject of chemical investigations that have led to the characterization of their secondary metabolites. Plants of the genus with the identified phytoconstituents, including phenylpropanoid glycosides (PhGs), terpenoids, phytosterols, lignans, quinones, and flavonoids, have been claimed to possess antiviral, antifungal, antiprotozoal, analgesic, antiinflammatory, and cytotoxic activities. In vitro and in vivo pharmacological research studies have reported the validation of the medicinal properties of plants of this genus. The present review analyzes published data from the ethnomedicinal, phytochemical, and pharmacological studies of plants of the genus Markhamia.

Key words: Ethnomedicine, ethnopharmacology, Markhamia, phytochemistry

INTRODUCTION
Markhamia (Seemann ex K.Schum) is a genus of flowering plants in the family Bignoniacae with about 100 genera and 800 species. Markhamia has been reported among other genera of the family in Nigeria and 10 species are widely distributed in tropical Africa and Asia.¹,² The genus was named by Berthold Seemann, in honor of Sir Clements Robert Markham (1830–1916), who introduced the well-known quinine-yielding Cinchona into India.³ Plants of this genus are trees or shrubs with opposite, compound imparipinnate leaves and yellow-green flowers grown mostly for social, agrihorticultural, and medicinal purposes.⁴ They are mostly found in fringing forests and are drought-resistant. The roots, barks, stems, and leaves of Markhamia species have been used by traditional healers for the treatment of miscellaneous disease conditions such as microbial and parasitic diseases, anemia, diarrhea, backache, sore eyes, intercostal pain, pulmonary troubles, gout, scrotal elephantiasis, rheumatoid arthritis, and external skin diseases.⁵-¹¹ The plant has also been used in the treatment of diarrhea, dysentery, pain, and inflammation in veterinary patients.¹²,¹³ The therapeutic value of plants used in traditional medicine is due to the presence of phytochemical compounds that are found in parts of the plants; moreover, a medicinal plant is a plant whose biological activity has been ethnobotanically reported and scientifically established.¹⁴,¹⁵ Preliminary phytochemical investigations of Markhamia species have shown the presence of biologically active substances such as flavonoids, saponins, steroids, terpenes and terpenoids, phytosterols, tannins, phenols, coumarins, and quinones.²,¹⁶,¹⁷ In support of the significance of the genus Markhamia, diverse pharmacological investigations have been reported in the literature.¹⁸-²¹ The isolation and identification of various chemical constituents from different plant parts of species including their pharmacological effects have been reported.

This review aims to provide a comprehensive and up-to-date report on species of the genus Markhamia with emphasis on the ethnomedicinal uses, the phytochemical and pharmacological studies, and highlights of research reports on the isolation, characterization, and identification of various active constituents present in the plant.

ETHNOMEDICINAL USES
The medicinal uses of plants range from administration of the various plant parts (alone or in combination with other plant parts) to the use of decoctions and extracts from the plants.²²,²³ Plants of the genus Markhamia have been used by different tribes in various parts of African and Asian countries. Details of the uses of Markhamia species and the associated references are indicated in Table 1.

PHYTOCHEMISTRY OF MARKHAMIA SPECIES

Chemical investigations of different plant parts of the Markhamia species Markhamia lutea (Benth.) K.Schum [Figure 1], Markhamia obtusifolia (Baker) Sprague [Figure 2], Markhamia stipulata (Wall.) Seem [Figure 3], Markhamia tomentosa (Benth.) K.Schum. ex Eng [Figure 4], and Markhamia zanzibarica (Bojer ex D.C.) K.Schum [Figure 5] have led to the characterization of various secondary metabolites. These chemical constituents have been categorized as phenylpropanoid glycosides (PhGs), alkaloids, terpenoids, phytosterols, quinones, lignans, and flavonoids. The known PhGs verbacoside (1) and isoverbacoside (2) and three new PhGs lutosides A–C (3–5) were isolated from the roots of Markhamia lutea. This was followed by the isolation of five new verbacoside derivatives: Markhamiosides A–E (6–10) and 13 known compounds from the leaves and branches of Markhamia stipulata. The characterization and identification of acteoside, also known as verbacoside (1) and isacteoside (2), in the ethyl-acetate fraction of the leaves of Markhamia tomentosa have been reported.

CLASS OF SECONDARY METABOLITES COMMON TO MARKHAMIA SPECIES

Phenylpropanoid glycosides

PhGs are acetylated glycoconjugates with the core structure [Figure 6] characterized by a hydroxyphenylethyl aglycone linked to a β-glucopyranose through glycosidic linkage. The glucose residue of the core structure is often encircled with substituents such as aromatic acids (cinnamic acid, ferulic acid, isofeurlic acid, and caffeic acid) and various sugars (apiose, arabinose, rhamnose, galactose, and xylose) through ester and glycosidic linkages, respectively. Isolation of PhGs from the genus Markhamia was reported for the first time by Kernan et al. The known PhGs verbacoside (1) and isoverbacoside (2) and three new PhGs lutosides A–C (3–5) were isolated from the roots of Markhamia lutea. This was followed by the isolation of five new verbacoside derivatives: Markhamiosides A–E (6–10) and 13 known compounds from the leaves and branches of Markhamia stipulata. The characterization and identification of acteoside, also known as verbacoside (1) and isacteoside (2), in the ethyl-acetate fraction of the leaves of Markhamia tomentosa have been reported.

Terpenoids and phytosterols

Terpenoids including their oxygenated, hydrogenated, and dehydrogenated derivatives are naturally occurring hydrocarbon molecules that are built up of isoprene units (C₆H₁₂) n joined in a head-to-tail fashion. Terpenoids are classified based on the number of isoprene units into monoterpenoids C₁₀, sesquiterpenoids C₁₅, diterpenoids C₂₀, sesterterpenoids C₂₅, triterpenoids C₃₀, carotenoids C₄₀, and phytosterols are among the subclass of terpenoids and are derived from tetracyclic triterpenes. Six cycloartane triterpenoids [Figure 7], that is, musambins A–C (19–21) and their 3-O-xyloside derivatives musambiosides A–C (22–24), along with other with pentacyclic triterpenes [Figure 8], that is, 2-epi-tormentic acid (25) and arjunic acid (26), were reportedly isolated from the ethylacetate leaf extract of...
Markhamia lutea. Three bioactive pentacyclic triterpenoids [Figure 8], that is, epi-tormentic acid (25), ursolic acid (29), and pomolic acid (30) were isolated from the leaves of Markhamia obtusifolia. Gamma-sitosterol (38), campesterol (39), and tritriacontane (40) were isolated from the root, stem bark, and leaves of Markhamia zanzibarica, respectively. Additionally, the isolation of pentacyclic triterpenoids such as pomolic acid (30), oleanolic acid (33), tormentic acid (35), and β-sitosterol (28) and its derivatives has been reported from the stem bark of Markhamia tomentosa. Ajugol (31), tormentic acid (35), carnasol (36), and oxopomolic acid (37) were identified in the leaves of M. tomentosa. The structures of the compounds were established by proton nuclear magnetic resonance (1H-NMR) and carbon-13 nuclear magnetic resonance (13C-NMR)—including one- and two- dimensional techniques—spectroscopy and mass spectrometry.

Lignans
Lignans are dimeric compounds formed by the union of two molecules of a phenylpropene derivative. The lignans paulownin (41) and palmitone (42), as well as palustrine, have been isolated from the stem heartwood of *Markhamia stipulata* and *Markhamia tomentosa*, respectively.

Quinones
Quinones are derived from benzoquinone, naphthoquinone, or anthraquinone structural moieties. Four lapachol-type naphthoquinones (43–46) and markhamioside F (48) were isolated from the stem heartwood of *Markhamia stipulata*. Two bioactive naphtho[2,3-b] furan-4,9-diones [Figure 9a], that is, 2-acetylnaphtho[2,3-b] furan-4,9-dione (49) and 2-acetyl-6-methoxy-naphtho[2,3-b] furan-4,9-dione (50) were reported to have been isolated from the stem bark of *Markhamia tomentosa*. In addition, dilapachone (51) [Figure 9b] was identified in the ethyl-acetate fraction of the leaves of *Markhamia tomentosa*.

Flavonoids
The identification of luteolin (52), luteolin-7-rutinoside (53), and luteolin-3',7-di-O-glucoside (54) [Figure 10] from the ethyl-acetate fraction of the leaves of *Markhamia tomentosa* has been reported.
ETHNOPHARMACOLOGICAL ACTIVITY

The primary metabolites are mainly important to the plants, while the secondary metabolites are of medicinal value for humans.13 The medicinal plants of the genus *Markhamia* have emerged as a good source of medicines. Researchers have carried out various *in vitro* and *in vivo* screenings on the extracts and isolated compounds from members of the genus to authenticate their use in traditional medicine. Plants of this genus have demonstrated a wide spectrum of pharmacological profiles such as antiulcer, antioxidant, antimicrobial, antiinflammatory, analgesic, and antiviral activities. In our earlier work,14 we reported the
cytotoxicity and the antiproliferative and apoptosis-inducing activity of one member of the genus *Markhamia* against brine shrimp larvae and HeLa cervical cancer cell lines. The following section presents a review of ethnopharmacological uses of *Markhamia* species. More details of the pharmacological properties of these species and the associated references are shown in Table 3.

**M. lutea** (Benth. ) K.Schum

The roots of *Markhamia lutea* are soaked in cold water for 30 min and the resulting tea is used to reduce symptoms of watery and bloodless diarrhea.\(^{[23]}\) The aqueous extract of the root bark is used in the treatment of anemia and diarrhea.\(^{[9]}\) *Markhamia tomentosa* and *Markhamia tomentosa* leaves in *in vitro* showed <50% cell proliferation of one cancer cell line out of three. *In vitro* extracts and pure compounds inhibited growth of *Markhamia tomentosa*. *In vivo* methanol extract showed selective cholinesterase inhibitory activity toward butyrylcholinesterase enzyme. *Markhamia obtusifolia* leaves and roots exhibited cytotoxic effect against A431 human skin carcinoma cell lines. The following section presents a review of pharmacological investigation of *Markhamia* species. More details of the pharmacological properties of these species and the associated references are shown in Table 3.

</tbody>
</table>
exhibited mild antileishmanial and antitrypanosomal activities.[27] Dichloromethane leaf extract of the plant showed weak antiplasmodial activity with a half maximal inhibitory concentration (IC₅₀) value of 29 μg/mL.[19] The cytotoxic potential of the methanolic root extract of *Markhamia hildebrandtii* (synonym of *Markhamia lutea*) was investigated against cervical carcinoma, colon adenocarcinoma, and skin carcinoma.[18] In vivo pharmacological screening of the leaf extract of *Markhamia platycalyx* (synonym of *Markhamia lutea*) provided evidence that the plant has high potential as an anti-Alzheimer's disease drug lead due to its high phenolic content.[21]

**M. obtusifolia** (Baker) Sprague

The root of *Markhamia obtusifolia* is used in folk medicine to treat tuberculosis infection of lymph nodes in the neck,[38] convulsion in children,[18] and hookworm infestation.[19] The roots, barks, and leaves are boiled with other plants and used as an inhalant for the treatment of colds. In ethnoveterinary medicine, the leaves and fruits of this species are consumed as fodder by goats.[40] The methanolic root extract of *M. obtusifolia* exhibited minimal cytotoxic effect (<50% cell proliferation) against A431 skin carcinoma at 100 μg/mL.[18] The antifungal activity of three isolated triterpenoids (25, 29, and 30) from the acetone extract of *M. obtusifolia* has been reported.[31] The claimed anthelmintic activity of this plant species has been confirmed *in vitro*. Further research is required to confirm the folk uses of the plant in treating other disease conditions.

**M. stipulata** Seem. ex K.Schum.

The leaves and barks of *Markhamia stipulata* are used externally for the treatment of skin diseases and internally as an analgesic [Table 1]. Bioactive chemical compounds including quinones, phytosterols, lignans, and PhGs have been isolated from different parts of the plant.[7,33] Although the pharmacological activity of the compounds isolated from the plant has not been investigated, the pharmacological activities of verbascoside derivatives have been reported to have antifungal, antibacterial, antiviral, and analgesic effects.[30,41,42]

**M. tomentosa** (Benth.) K.Schum. ex Engl.

Of all the members of the *Markhamia* genus, the traditional use of the different plant parts of *Markhamia tomentosa* is the most reported [Table 1]. The species has found use in both human folk and ethnoveterinary medicines.[10,19] The plant is used in ethnoveterinary medicine to control gastrointestinal ailment and in pain management.[12,13] Preliminary phytochemical investigations of the leaves revealed the presence of major classes of bioactive compounds including saponins, flavonoids, terpenes, steroids, and phenolic nuclei.[26,46] A number of *in vitro* and *in vivo* studies have been carried out to validate the activity of the plant. Two naphthoquinone [Figure 9] compounds (49–50) isolated from the stem bark of *M. tomentosa* exhibited potent antiprotozoal activity against *Plasmodium falciparum*, *Leishmania donovani*, and *Trypanosoma brucei rhodesiense*. The leaf extract of the plant was reported to possess strong antimicrobial and antioxidant effects.[8] The inhibition of *Escherichia coli* by the hexane and ethylacetate extracts of *M. tomentosa* justifies the traditional use of the plant in the management of dysentery and diarrhea.[2] Although hepatoprotective activity has not been reported for this plant species, there has been a report on the prophylactic and therapeutic activities of a member of the family Bignoniaceae against paracetamol-induced liver damage in rats.[48] Alcoholic extracts of the leaves of *M. tomentosa* were shown to have potent analgesic and antiinflammatory effects[18,19] on rats and mice. The selective inhibition of butyrylcholinesterase enzymes by the root bark of this species in the management of Alzheimer's disease has also been reported.[18,45] Ethanol crude extract and the different solvent fractions of *M. tomentosa* leaves were reported to prevent gastric mucosal ulceration in the stomachs of rats.[20] In our earlier work,[20] we reported the cytotoxicity activity and underlying mechanisms of *Markhamia tomentosa* leaf extract on brine shrimp larvae, HeLa and MCF-7 cancer cell lines, and noncancerous Vero cell lines. In view of the wide application of this plant species and the tendency for prolonged intake, we are currently investigating the dose- and time-dependent chronic toxicity effects of *Markhamia tomentosa* in rodents (not published).

**M. zanzibarica** (Bojer ex DC.) K.Schum.

*Markhamia zanzibarica* is widely distributed in tropical Africa and Asia. In India, the plant is the second most reported *Markhamia* species after *Markhamia lutea*.[45] The plant is used to treat toothache, headache, and general pains [Table 1]. The cytotoxic effect of this species on *Artemia salina* has been investigated[49] and the activity was attributed to the bioactive gamma-sitosterol (38) compound isolated from the root of the species.[26]

**CONCLUSION**

This review summarizes information on the plants of the genus *Markhamia* with emphasis on their ethnomedicinal uses, isolated phytoconstituents, and ethnomedical and pharmacological studies on them. Species of this genus have been useful in the management of various disease conditions in both human and veterinary traditional medicines. Some of the claimed traditional uses have been validated through phytochemical and pharmacological studies of the genus. On preliminary phytochemical screening of plants of this genus, the presence of a wide range of secondary metabolites was reported. However, the major reported class of phytoconstituents, isolated through various separation and purification techniques from *M. lutea*, *M. obtusifolia*, *M. stipulata*, *M. tomentosa*, and *M. zanzibarica*, were PhGs, terpenoids, phytosterols, lignans, quinones, and flavonoids. The isolated compounds were identified on analysis of their spectroscopic and chemical data, which were consistent with values reported in the literature. A number of *in vitro* and *in vivo* pharmacological studies have confirmed that the plant extracts and isolated compounds possess significant antiviral, antiprotozoal, antimicrobial, antioxidant, analgesic, antiinflammatory, anti-Alzheimer, antiulcer, and cytotoxic activities. It may be concluded that plants of this genus hold great potential as a source of new drugs. Thus, further studies aimed at the proper documentation of folk uses, validation of the claimed bioactivities, and isolation and identification of the bioactive compounds of species of the genus are required.
